

# Organic Synthesis

How can we form this?

Substitution?  $\text{Br}-\text{CH}=\text{CH}-\text{CH}_2-\text{CH}_3$   
 No; the pi bond will break before Br contributes to a substitution reaction

We could use hydrogenation of 1-bromo-1-butyne (provided only one of the pi bonds break)

Performing an elimination on 1-bromo-2-butanol or **1-bromo-1-butanol** would work best.

Best choice: only one product possible.

### How do we choose between reactions?

Notice that there may be more than one way to form a particular compound

The handout is an oversimplification ...

There are thousands of reaction mechanisms, many of which are very specific

Considerations when choosing include ...

- Yield (how much product forms)
- Potential for multiple products
- Ease of separating contaminating structures
- Type of isomer desired
- Economics: e.g. cost of starting materials

### Answers: 1, 2

1) An addition reaction involves breaking a double bond and adding two parts of a molecule across the bond

- Examples: 1) halogenation, 2) hydrogenation, 3) hydrolysis, 4) addition polymerization
- The 'opposite' of breaking the bond is forming a double bond - i.e. elimination

2) Condensation is a reaction that involves the production of water.

- Examples: 1) elimination, 2) esterification, 3) condensation polymerization
- oxidation is not an example - the  $\text{H}_2\text{O}$  comes from  $\text{H}_2\text{SO}_4$ , not from an organic molecule

### Answers: 3

a) **1,2-dichlorocyclopentane** is best formed via halogenation of cyclopentene. Substitution using  $\text{Cl}_2$  would work, but would not be efficient because many other products would form (e.g. 1,2,4-trichlorocyclopentane, etc.)

b) The only way to prepare **octane** from 4-octyne is via hydrogenation of both pi bonds.

b)  $\text{H}-\text{C}(\text{H})-\text{C}(\text{H})-\text{C}(\text{H})-\text{C}\equiv\text{C}-\text{C}(\text{H})-\text{C}(\text{H})-\text{C}(\text{H})-\text{C}(\text{H})-\text{H} + \text{H}_2$   
 $\xrightarrow{\text{Room temp.}}$   $\text{H}-\text{C}(\text{H})-\text{C}(\text{H})-\text{C}(\text{H})-\text{C}(\text{H})-\text{C}(\text{H})-\text{C}(\text{H})-\text{C}(\text{H})-\text{C}(\text{H})-\text{H}$

c) **2,2,3,3-tetrabromopentane** can be formed via substitution using  $\text{Br}_2$ . It is more efficiently formed via the halogenation of 2-pentyne

$\text{H}-\text{C}(\text{H})-\text{C}\equiv\text{C}-\text{C}(\text{H})-\text{C}(\text{H})-\text{H} + \text{Br}_2 \xrightarrow{\text{Room temp.}} \text{H}-\text{C}(\text{H})-\text{C}(\text{Br})_2-\text{C}(\text{Br})_2-\text{C}(\text{H})-\text{H}$

d) **1-butene** can be formed from the elimination reaction involving 1-butanol. Using 2-butanol could result in either 1-butene or 2-butene and therefore is a less desirable choice.

e) **Propanoic acid** is best formed from the oxidation of propanal

f) **Ethanol** is most easily formed from the hydrolysis of ethene.

g) **Ethyl propanoate** is an ester, formed via esterification (ethanol plus propanoic acid)

### Formation of a polyamide

A polyamide "backbone" forms with R groups coming off. This protein is built with amino acids.
